

Investigations of Lignocellulosic Materials from Rape for the Purpose of Producing Composites with Thermoplastic Polymers

Introduction

On the basis of preliminary investigations, we concluded that the lignocellulosic material from rape is suitable for developing composites with isotactic polypropylene [3]. During investigations into new kinds of composites, it is important to characterise the components used. World crops of rape are estimated at over 36 million tons, which means that this fibre may become a significant source of lignocellulosic materials.

Since cellulose plays an important role as a skeletal component in wood fibres, and has an impact on their mechanical properties [1], an analysis was carried out to determine the content of cellulose in rape stems.

Abstract

So far we know of no complex investigations defining lignocellulosic materials obtained from the stem of rape for the purpose of application in composites with thermoplastic polymers. This study is concerned with investigating the morphology of the rape stem, and the cellulose content in the wooden parts of the rape stem. Investigations with a microscope of the structure of the rape stems and the thickness of the wooden layers for various winter seed oil varieties were carried out. On the basis of the analytical results, it has been found that the average cellulose content in the wooden parts of the winter rape stem ranges from 35% to 40%. The amount of the cellulose in rape in comparison with the amount of cellulose in various species of wood is comparable. The structural investigations confirmed the presence of cellulose I. The X-ray patterns in the internal and external areas of the wooden parts of the stem are similar.

Key words: rape, composites, polypropylene, structure, PLM, SEM, WAXS.

Up to now, only one study [2], published in the 1960s, has described the morphology of the rape stem. Therefore, it would be advisable to characterise this structure in the context of using the wooden parts of the rape stem as a source of lignocellulosic material to be used in producing composites with thermoplastic polymers.

Our previous investigations on composite rape stem/isotactic polypropylene confirm the good mechanical properties of this new composite material [3].

This study is concerned with investigating the morphology of the rape stem and the content of cellulose in the wooden parts of the rape stem.

Experimental

In order to characterise the morphology of the rape stem and the cellulose content in the wooden parts of the rape stem, we analysed three winter oilseed rape varieties: the German Lisek, the French Casek and the Polish Kaszub. The Polish rape used came from the Plant Breeding and Acclimatisation Institute (IHAR) fields in Poznań and grew in 2003. For our studies we used dried rape stem that had been stored for 6 months.

The percentage content of the cellulose from the wooden parts of the rape stems was analysed by means of the analytical methods described earlier [2,4].

The anatomical structure of the rape stems was examined by means of optical mi-

croscopy (a Biolar PI polarising-interferencing microscope connected to a Minolta 300X camera) and electron microscopy (Philips SEM 515) methods, using a voltage of 15 kV.

The structural investigations of rape stems were carried out by means of the wide-angle X-ray scattering method (WAXS), using CuK α radiation. The samples were prepared in the following way: the stem was cut lengthwise, the soft tissue (parenchyma) was then removed, and the flat surfaces obtained in this way were examined on both sides.

Results

The microscope investigations characterised the structure of the rape stems and thickness of the wooden layers in each of the mentioned varieties. The images (Figures 1-4) show the stems after they matured that is this sort of sample which is used as raw material for production of the composites.

As we can see from optical microscope images, the inside of the stem is parenchyma. As regards the outside part of the stem, this represents the wooden part of the stem. This is also shown on the images obtained by the electronic microscope method (Figures 3,4). Figure 1 shows a microscope picture of the Lisek varieties, and Figure 2 shows the Kaszub varieties. A cross-section of the whole rape stem is shown in Figure 3 (for the Casek varieties). All the samples display a similar stem structure.

On the basis of the photographs taken of the samples, we can establish that the thick-

Table 2. The amount of the cellulose in various species of the wood [1].

Species of the wood	Amount of the cellulose [%]
pine	41.9 – 54.2
spruce	38.1 – 58.0
oak	46.6
white willow	37.2 – 50.0

ness of the wooden layers falls within a wide range of 0.2 to 0.7 mm (Figures 1-4). Before the samples were tested for cellulose content, we decided to establish the percentage of the wooden part of the stem. This showed that the amount of the wooden substance in the rape stem exceeds 80% for all varieties (except for parenchyma).

We used a method for estimating the cellulose in rape stems which was based on separating the cellulose of other compounds (mainly lignin) in an acid mixture of acetylacetone and 1,4-dioxane [1,4]. On the basis of the analytical results, it has been found that the average cellulose content in wooden parts of winter rape stem are as follows: for Lisek: 35.1%; for Kaszub 36.8% and for Casek 37.1% (Table 1) [5].

Table 2 shows the average content of cellulose in various species of woods: pine, oak, spruce and white willow [1].

As is known, wood is a valuable lignocellulosic material used for manufacturing composites [6,7,8]. As shown in the comparison in both tables, the amount of the cellulose in wood is comparable to that in the rape stem.

As shown in Figures 1-4, the structural element which is the source of lignocellulosic materials is the wooden part of the stem.

The lignification process of the stem's inside layer progresses along with the growth of the plant. The size of the layer increases because of the lignification of the soft tissue of the core. For that reason, the structure of both the interior and exterior of the stem was checked.

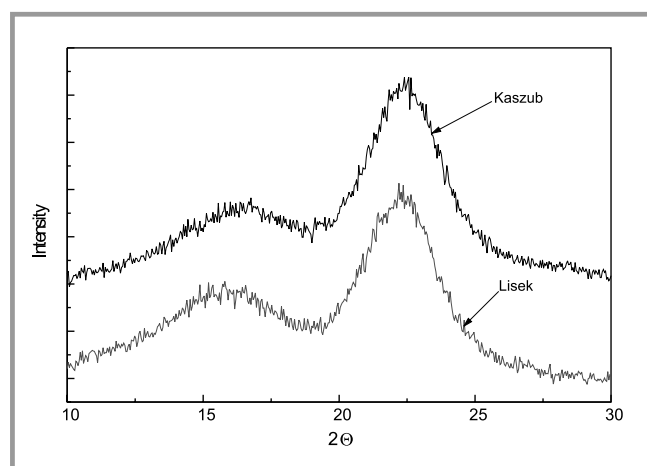

Figure 5. X-ray patterns of outside layers of rape stem (Lisek and Kaszub varieties).

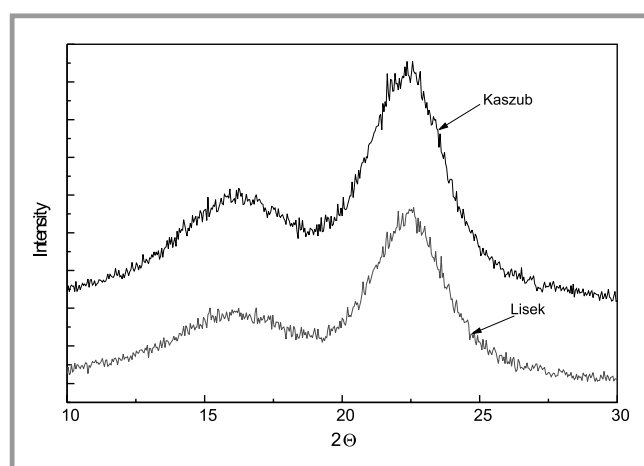

Figure 6. X-ray patterns of inside layers of rape stem (Lisek and Kaszub varieties).

Figure 5 shows the X-ray patterns of the outside part of the Lisek (lower graph) and Kaszub varieties (upper graph). On Figure 6 the X-ray patterns from the other side are presented.

As we could expect, the X-ray picture represents a typical image of cellulose I [8,9]. As shown in the comparison of both X-ray patterns, there were no significant differences between the varieties. The comparison of X-ray patterns stems from both the inside and outside shows that the crystalline structures are similar.

Conclusions

- The thickness of the wooden layers in rape stems determined by microscopic methods is in the range of 0.2 – 0.7 mm.
- The content of the cellulose in rape is comparable with the content of the cellulose in other lignocellulosic materials used for manufacturing composites.
- The X-ray patterns of wooden rape stems from both the inside and outside are similar, and confirmed the presence of cellulose I.

INSTYTUT WŁÓKIEN CHEMICZNYCH
INSTITUTE OF CHEMICAL FIBRES
ŁÓDŹ, POLAND Established in 1952

The **Institute of Chemical Fibres** specialises in scientific and technological research in natural and synthetic polymers and man-made fibres, including among others the following:

- modification and utilization of natural and synthetic polymers, e.g. cellulose, lignin, chitin, chitosan, starch, alginates, keratin, polyamides, polyester, polypropylene, etc.;
- classical, modified and new generation man-made fibres manufactured from natural and synthetic polymers, such as cellulose, cellulose carbamate, chitosan, polyamide, polyacrylonitrile, polyester, and polypropylene, especially alternative technologies of cellulose fibres, such as cellulose fibres made from direct soluble cellulose;
- special fibres and fibrous materials from different polymers, fibres and fibrous materials for medicine, food industry, agriculture, and technics;
- biotechnology methods for synthesis and processing of polymers and fibres;
- biodegradable polymers and fibres, and their applications in medicine, technics, and agriculture;
- biomaterials including biopolymers;
- utilization of polymeric wastes and by-products;
- use of special polymeric materials for environmental protection.

The **Institute of Chemical Fibres** offers:

- new technologies based on own research, as well as in cooperation with other Polish and foreign research centres and companies;
- improvements for existing technologies;
- technologies and techniques in laboratory scale and up-scaling to commercial units.

The **Institute of Chemical Fibres** provides services in:

- metrological analyses (in the Accredited Analytical Laboratory);
- microbiological analyses (in the Accredited Analytical Laboratory);
- physical-chemical analyses, e.g. gel permeation chromatography for synthetic and natural polymers (according to GLP system);
- biodegradation tests for polymers.
- scientific, technical, standardization and patent information;

The **Institute of Chemical Fibres** also offers production and delivery of specialty products, for example special polymeric materials for medicine and pharmacy.

The **Institute of Chemical Fibres** maintains wide contacts and cooperates with research centres, universities, and industry in Poland and in many other countries like Austria, China, Finland, France, Germany, Japan, Norway, and the USA.

The **Institute of Chemical Fibres** participates in international research programmes. In recent years, the Institute participated in the EUREKA, COPERNICUS and MARIA SKŁODOWSKA-CURIE European Scientific Programmes, and at present the Institute participates in the NATO SPP (Science for Peace), COST 628, and COST 847 programmes, as well as in EC projects on the basis of the 5th and 6th Frame Programmes.

During the 48th World Exhibition of Invention, Research and Industrial Innovation, Brussels Eureka'99 the **Institute of Chemical Fibres** was awarded the "Croix de Chevalier" of the Kingdom of Belgium for the entire significant inventive activity presented at the Brussels World Exhibitions during 1992-1998; whereas during the 50th WEIRII, Brussels Eureka'2001, the late Professor Henryk Struszczyk, the Managing Director of the Institute over the years 2002-2005 was also awarded the 'Croix de Chevalier' for his entire outstanding inventive activity. Over the years 1992-2004 the Institute was awarded 5 gold and 6 silver medals, mainly in the fields of biotechnology, medical textile products, and environmental-friendly manufacturing technologies.
